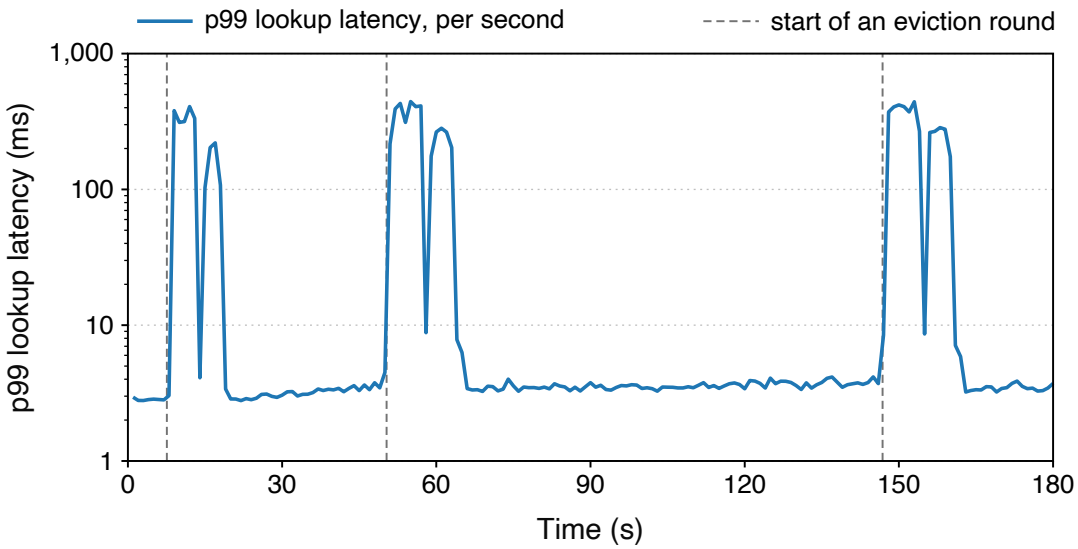
With a full pool, every eviction round stalls lookups for 10–15 s



- **Setup.** 100M objects of 1 MiB; the pool sits at its 90% eviction watermark. 16 clients write, 16 look up recent objects.
- **Each round** scans all 100M keys twice with 16 threads, locking each shard exclusively.
- **Result.** Lookup p99 rises from 3.5 ms to 440 ms for 10–15 s per round; writes stop; 6% of writes are rejected.
- **Why it is central.** One process holds every key, so eviction scans everything on the cores and locks that serve lookups.

Patched master, 16 cores of an AMD EPYC 7702; one 180 s run; p99 per second of 128-key lookups.
